Content Approval Workflow

Magnolia (DX Core) comes with a four-eye content approval workflow configured on the Pages app.

For custom content-apps, the publish/unpublish configuration (availability, type, dialog, label, etc) is defined within the actions definition and the action bar definition

Developer Side

Custom App

For a Magnolia content app, add four-eyes workflow by replacing direct publish/unpublish actions with workflow dialog actions.

```
subApps:
  browser:
    actions:
      activate: !override
        $type: openDialogAction
        dialogId: workflow-pages:publish
        icon: icon-publish
        availability:
          rules:
            notDeleted: &notDeleted
              $type: jcrIsDeletedRule
              negate: true
            isPublishable: &isPublishable
              $type: jcrPublishableRule
      activateRecursive: !override
        label: Publish incl. subnodes
        $type: openDialogAction
        dialogId: workflow-pages:publishRecursive
        icon: icon-publish-incl-sub
        availability:
          rules:
            notDeleted: *notDeleted
            hasSubPages:
              $type: jcrHasChildrenRule
              nodeTypes:
                - mgnl:folder
                - mgnl:card
            isPublishable: *isPublishable
      deactivate: !override
        $type: openDialogAction
        dialogId: workflow-pages:unPublish
        icon: icon-unpublish
        availability:
          rules:
            notDeleted: *notDeleted
            isPublished:
              $type: jcrPublishedRule
```

Out-of-the-Box App

For an existing OOTB app, use a decoration file instead. For example, to enable the workflow for the assets app.

```yaml
# light-modules/spg-decorated/decorations/dam-app/apps/dam.yaml
subApps:
  jcrBrowser:
    actions:
      publish: !override
        $type: openDialogAction
        dialogId: workflow-pages:publish
        icon: icon-publish
        availability:
          rules:
            notDeleted: &notDeleted
              $type: jcrIsDeletedRule
              negate: true
            isPublishable: &isPublishable
              $type: jcrPublishableRule

      publishRecursive: !override
        $type: openDialogAction
        dialogId: workflow-pages:publishRecursive
        icon: icon-publish-incl-sub
        label: Publish with subpages
        availability:
          rules:
            notDeleted: *notDeleted
            hasSubPages:
              $type: jcrHasChildrenRule
              nodeTypes:
                - mgnl:folder
                - mgnl:asset
            isPublishable: *isPublishable

      unpublish: !override &unpublish
        $type: openDialogAction
        dialogId: workflow-pages:unPublish
        icon: icon-unpublish
        availability:
          rules:
            notDeleted: *notDeleted
            isPublished:
              $type: jcrPublishedRule

      publishDeletion: !override
        $type: openDialogAction
        dialogId: workflow-pages:publishDeletion
        icon: icon-delete
        availability:
          rules:
            isDeleted:
              $type: jcrIsDeletedRule

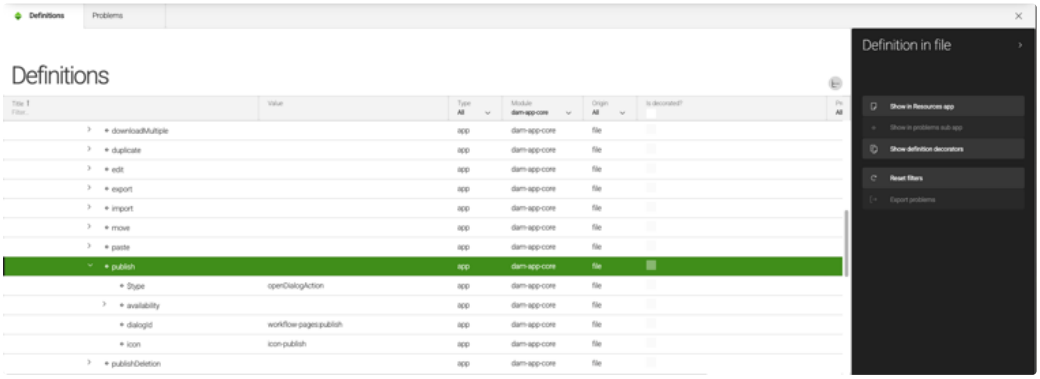
```

Use the `module.yaml` file to ensure that the decoration is loaded after all other modules; otherwise, it may cause conflicts or overrides.

```yaml
# light-modules/spg-decorated/module.yaml
version: 1.0
dependencies:
  core:
```

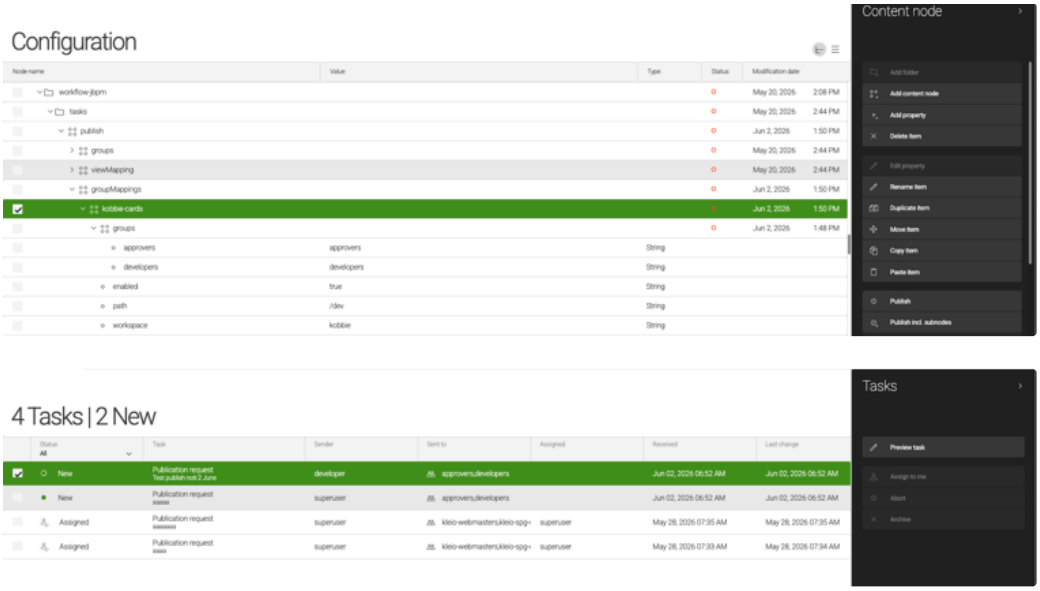
```
    version: 6/*
  workflow-pages:
    version: 6/*
```

The decoration can be verified using the Definitions app.



Approver Side

Create a new group mapping at `/modules/workflow-jbpm/tasks/publish/groupMappings` in the Configuration app. New publish events will be notified to all these groups.



To allow a role to claim the task for further publishing, quick aborting or archiving, configure permissions in the task app.

```yaml
# light-modules/spg-decorated/decorations/tasks-app/apps/tasks-app.yaml
subApps:
  browser:
    actions:
      claim:
        availability:
          access:
            roles:
```

```
            - approver
            - superuser
      abort:
        availability:
          access:
            roles:
              - approver
              - developer
              - superuser
```

To configure permissions on the Task Preview (Publication Request) screen for actual Publish, Reject, or Abort actions, decorate the workflow module:

```yaml
# light-modules/spg-decorated/decorations/workflow/messageViews/publish.yaml
# light-modules/spg-decorated/decorations/workflow/messageViews/unpublish.yaml
actions:
  review:
    availability:
      access:
        roles:
          - superuser
          - approver
  claim:
    availability:
      access:
        roles:
          - superuser
          - approver
  approve:
    availability:
      access:
        roles:
          - superuser
          - approver
  confirmRejection:
    availability:
      access:
        roles:
          - superuser
          - approver
  retry:
    availability:
      access:
        roles:
          - superuser
          - approver
  abort:
    availability:
      access:
        roles:
          - superuser
          - approver
          - developer
```

Appendix: App Visibility

To allow a role to see a panel (a group of apps), configure the permission at

`light-modules/spg-decorated/decorations/admincentral/config.yaml`

```yaml
groups:
    - name: kobbie
      label: Kobbie's Apps
      apps:
        - name: cards-app
      permissions:
        roles:
          superuser: superuser
          developer: developer
          approver: approver

```

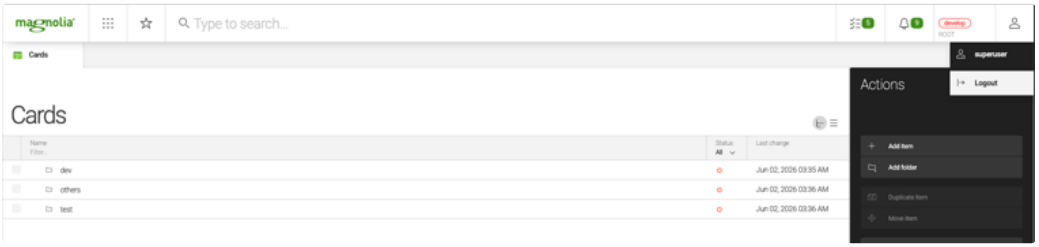
To allow a role to see an app, configure the app permission

```yaml
# light-modules/kobbie/apps/cards-app.yaml
!content-type:card
name: cards-app
label: Cards
icon: icon-templating-app
permissions:
  roles:
    - superuser
    - developer
    - approver
```

To allow a role to read/write in an app, configure the Role ACLs in the Security app. This rule allows the `developer` role to read and write in the /dev folder and all of its child items.

> The workspace name is defined in the Content Type YAML file.

From the superuser perspective, the cards app looks like this.



But on the developer side, only the dev folder is shown.
